13. Matrix Operations	18

1. Creating Vectors and Matrices

Row vectors: there are many ways of creating a vector

Explicit list

```
>> x=[0 1 2 3 4 5]; % What happens if you skip the semicolon?
>> x=[0,1,2,3,4,5]; % Inserting commas doesnt change anything
```

Using a:increment:b

```
>> x= 0:0.2:1; % same as x=[0 0.2 0.4 0.6 0.8],
>> x= a:Δx:b; % x=[a,a+Δx, a+2Δx, a+3Δx, ..., b]
% that is, vector from a to b in increments of size Δx
% What happens if Δx is not a integer divisor of b-a?
```

Using linspace(a,b,n)

```
>> x= linspace(0,1,6); % vector containing 6 points on interval [0,1]
>> a=0;b=1;n=6; % Set variables
>> x= linspace(a,b,n); % vector containing n points on interval [a,b]
% Note: spacing is Δx = 1/(n - 1)!
```

Using for loops

```
>> for i=1:10 % First example of a for loop. Note: 1:10=1:1:10
>> x(i)=i; % What happens if you skip semicolon??
>> end

>> a=0;b=1;n=10; delx=(b-a)/n; % Set variables
>> for i=1:n+1
>> x(i)=a+delx*(i-1); % index of x has to be an integer > 0
>> end
```

How long is the vector?

```
>> length(x)
>> d=size(x) % What are the entries in the matrix d?
```

Column vectors

Explicit list

```
>> x=[0;1;2;3;4]
```

Transposing a row vector

```
>> x=[0 1 2 3 4]' % Vectors are matrices. A'=transpose(A)
```

Matrices

Explicit list

```
>> A=[1 1 1; 2 0 -1; 3 -1 2; 0 1 -1];
```

Special matrices

```
>> x=zeros(1,4), y=zeros(4,1)
```

```
>> x=ones(1,4), y=ones(4,1)
```

2. Evaluating functions $y = f(x)$, manipulating vectors

Example

```
>> x=0:0.1:1;
>> y=sin(pi*x); % Type help elfun to see a list of predefined functions
```

Alternative, using a loop (much slower)

```
>> x=0:0.1:1;
>> n=length(x);
>> for i=1:n;
>>   y(i)=sin(pi*x(i));
>> end;
```

Vectors are matrices

```
>> y=x*x; % What happens? Why?
>> x2=0:0.2:1; y=x+x2; % What happens? Why?
>> y=x'*x % What is y ?
>> y=x*x' % What is y ?
```

Componentwise operation

```
>> y=x.*x % The dot denotes multiplication of components
>> y=x.^3 % The carat denotes exponentiation
>> y=2*x % Here you dont need a dot
>> y=1./x % Here you do
```

Accessing subvectors

```
>> x=0:0.1:1;
>> n=length(x)
>> x2=x(5:10) % What is x2?
>> x2=x([1,3,4,11]) % What is x2?
>> x2=x(2:4:11) % What is x2?
```

Accessing submatrices

```
>> a=[100 90 85; 117 110 108; 84 84 84; 96 90 88];
>> [m,n]=size(x)
>> a2=a(2,3) % What is the matrix a2?
>> a2=a(:,2) % What is a2?
```

```
>> a2=a(2,:)           % What is a2?  
>> a2=a(2:3,:)       % What is a2?  
>> a2=a(2:3,[1,3])   % What is a2?
```

The sum command (type 'help sum')

```
>> y=[1,4,2,10]; sum(y); % returns sum of all entries in vector y  
>> sum(y(1:2:4));       % what is it?  
>> sum(a(:,1));        % with a as before. what is it?
```

3. Plotting

Plot command

```
>> x=0:.1:1; y =sin(2*pi*x);  
>> plot(x,y);           % the two vectors have to have same dimensions
```

Exercise:

```
>> x=[0,1]; y=sin(2*pi*x);  
>> plot(x,y);           % What is going on??
```

Options

Line type options: -, : , -- , - .

```
>> plot(x,y,'-');  
>> plot(x,y,':');  
>> plot(x,y,'--');  
>> plot(x,y,'-.');
```

Color options: y,m,c,r,g,b,w,k

```
>> plot(x,y,'g');       % green line (line is default)  
>> plot(x,y,'r')
```

Marker options: .,o,x,+,*s,d,v,^,<,>,p,h (type help plot)

```
>> plot(x,y,'x');       % blue star (blue is default)
```

Using several options together

```
>> plot(x,y,'*-r');     % red line with star markers
```

Plotting several curves

```
>> x=0:0.05:1; y1=sin(2*pi*x); y2=cos(2*pi*x);  
>> plot(x,y1,x,y2)  
>> plot(x,y1,'-b',x,y2,'--r')  
  
>> x=0:0.05:2; y1=x; y2=x.^2; y3=x.^3; y4=x.^4;  
>> plot(x,y1,'-b',x,y2,'--r',x,y3,'*g',x,y4,'-c')
```

Alternative, using hold command

```
>> x=0:0.05:1; y1=sin(2*pi*x); y2=cos(2*pi*x);
>> plot(x,y1,'-b')
>> hold on
>> plot(x,y2,'--r')
>> hold off
```

The axis command

```
>> axis([0,2,0,4])
>> axis equal
>> axis square % Use 'help axis' to see what other options there are
```

Labelling

```
>> xlabel('time t')
>> ylabel('position s(t)')
>> ylabel('position s(t)', 'FontSize', 16)
>> title('Its important to label your graphs!')
>> text(0.6, 2, 'some text', 'FontSize', 16)
>> set(gca, 'FontSize', 16)
>> legend('x', 'x^2')
```

Simplest Plots

```
>> plot(x) % Plots x vs its index, quick way to see what is in x
>> plot(x1,x2) % Careful! This does not plot x1 vs index
>> % and x2 vs index. Instead, plots x2 vx x1
>> plot(x1,x2,x3) % and this gives you an error. Why?
```

4. Miscellaneous commands

Comments

```
>> % This is a comment
```

The help and lookfor commands

```
>> help zeros           % you need to know exact command name
>> help for
>> help                 % lists topics for which there is help
>> lookfor factorial    % if you do not know the exact command name
```

The print command

```
>> print                % prints current figure to current printer
>> print -deps          % prints current figure to .eps file
>> print -depsc         % prints current figure to color .eps file
>> print -dps           % prints current figure to .ps file
```

The figure command

```
>> figure               % opens new figure
>> figure(2)            % makes figure 2 the current figure
```

The pause command

```
>> pause                % What does this do?
>> pause(2)             % What does this do?
```

The continuation symbol

```
>> x=[0 1 2 3 4 5 ...   % To continue the current command
>> 6 7 8 9 10]          % to the next line, use ...
```

The hold command (see example in §3)

Further example, plot circle from $y = \sqrt{1 - x^2}, x \in [0, 1]$ (vL P1.2.3)

The clear command

```
>> clear                % clears all variables from memory
>> clear x y ...        % clears listed variables from memory
```

The clf command

```
>> clf                  % clears current figure
```

5. Scripts

You can type a string of commands into a file whose name ends in `.m`, for example `flnm.m`. If you then type

```
>> flnm
```

in your matlab window, it executes all the commands in the file `flnm.m`.

Make sure you document your script files! Add a few lines of comments that state what the script does.

6. Saving your work

Save all your script files on a floppy or CD-RW, preferably organized in directories (folders).

At the beginning of each in-class-programming session, transfer all necessary files or directories from your floppy (or from another UNM account using FsecureSSH) onto the local working directory.

In DSH 141, use E: as your working directory.

In ESCP 110, use Temp: as your working directory.

7. Timing your code, the commands `tic,toc`

```
>> tic           % starts stopwatch
>> statements
>> toc           % reads stopwatch
```

Exercise: Find out how much faster the vector operation

```
>> x=0:0.01:1;
is than the following statement of componentwise operations
>> for j=1:101;
>>   x(j)=(j-1)*0.01;
>> end;
```

Answer: (using old version of matlab) about 50 times faster! ⇒ MATLAB VECTO

8. Displaying Tables

Here is an example for how to neatly display a table of values using the `disp` command. Use `help disp` and `help sprintf` to see what these commands do.

```
>> disp(' j x sin(x)')
>> for k=1:n
>> disp(sprintf('%4d, %5.1f %10.4f',k, x(k),y(k)))
>> end
```

9. The for statement

```
>> % The command for repeats statements for a specific number of times.
>> % The general form of the while statement is
>>
>> FOR variable=expr
>>   statements
>> END
>>
>> % expr is often of the form i0:j0 or i0:l:j0.
>> % Negative steps l are allowed.
```

Example 1: What does this code do?

```
>> n = 10;
>> for i=1:n
>>   for j=1:n
>>     a(i,j) = 1/(i+j-1);
>>   end
>> end
```

10. The if statement

```
>> % The general form of the if statement is
>>
>> IF expression
>>   statement
>> ELSEIF expression
>>   statement
>> ELSE expression
>>   statement
>> END
>>
>> % where the ELSE and ELSEIF parts are optional.
>> % The expression is usually of the form
>> %           a oper b
>> % where oper is == (equal), <, >, <=, >=, or ~= (not equal).
```

Example 1: What does this code do?

```
>> n=10;
>> for i=1:n
>>   for j=1:n
>>     if i == j
>>       A(i,j) = 2;
>>     elseif abs(i-j) == 1
>>       A(i,j) = -1;
>>     else
>>       A(i,j) = 0;
>>     end
>>   end
>> end
>> end
```

Exercise 2: Define up-down sequence $x_{k+1} = \begin{cases} x_k/2 & \text{if } x_k \text{ is even} \\ 3x_k + 1 & \text{if } x_k \text{ is odd} \end{cases}$, x_0 given .

Write a script that builds the up-down sequence for $k \leq 200$.

Plot the solution vector $x(k), k = 1, \dots, 200$, for several initial conditions.

```
>> % You can also combine two expressions
>> % with the and, or, and not operations.
>> %
>> %      expression oper2 expression
>> %
>> % where oper2 is & (and), | (or), ~ (not).
```

Example 3: What does this code do?

```
>> for i=1:10
>>   if (i > 5) & (rem(i,2)==0)
>>     x(i)=1;
>>   else
>>     x(i)=0;
>>   end
>> end
```

11. The while statement

```
>> % The command while repeats statements an indefinite number of times,  
>> % as long as a given expression is true.  
>> % The general form of the while statement is  
>>  
>> WHILE expression  
>>   statement  
>> END  
>>
```

Example 1: What does this code do?

```
>> x = 4;  
>> y = 1;  
>> n = 1;  
>> while n<= 10;  
>>   y = y + x^n/factorial(n);  
>>   n = n+1;  
>> end
```

Remember to initialize n and update its value in the loop!

Exercise 2: For the up-down sequence $x_{k+1} = \begin{cases} x_k/2 & \text{if } x_k \text{ is even} \\ 3x_k + 1 & \text{if } x_k \text{ is odd} \end{cases}$, x_0 given .

Write a script that builds the up-down sequence while $x(k) \neq 1$ and $k \leq 200$, using the WHILE statement.

Plot the solution vector $x(k)$, $k = 1, \dots, 200$, for several initial conditions.

12. MATLAB Functions

MATLAB Functions are similar to functions in Fortran or C. They enable us to write the code more efficiently, and in a more readable manner.

The code for a MATLAB function must be placed in a separate `.m` file having the same name as the function. The general structure for the function is

```
function <Output parameters> = <Name of Function> (<Input Parameters>)  
%  
%  
% Comments that completely specify the function  
%  
<function body>
```

A function is called by typing

```
>> variable = <Name of Function>
```

When writing a function, the following rules must be followed:

- Somewhere in the function body the desired value must be assigned to the output variable!
- Comments that completely specify the function should be given immediately after the `function` statement. The specification should describe the output and detail all input value assumptions.
- The lead block of comments after the `function` statement is displayed when the function is probed using `help`.
- All variables inside the function are local and are not part of the MATLAB workspace

Exercise 1: Write a function with input parameters x and n that evaluates the n th order Taylor approximation of e^x . Write a script that calls the function for various values of n and plots the error in the approximation.

Solution: The following code is written in a file called `ApproxExp.m`:

```
function y=ApproxExp(x,n);
% Output parameter:  y (nth order Taylor approximation of e^x)
% Input parameters:  x (scalar)
%                   n (integer)

sumo = 1;
for k=1:n
    sumo = sumo + x^k/factorial(k);
end
y = sumo;
```

A script that references the above function and plots approximation error is:

```
x=4;
for n=1:10
    z(n) =ApproxExp(x,n)
end
exact=exp(4)
plot(abs(exact-z))
```

Exercise 2: Write the function `ApproxExp` more efficiently.

Exercise 3: Do the same as Exercises 1 and 2, but let x and y be vectors.

Example 4: An example of a function that outputs more than one variable. The function computes the approximate derivative of function `fname`, the error in the approximation, and the estimated error.

The following code is written in a file called `MyDeriv.m`:

```
function [d,err,esterr]=MyDeriv(f,fprime,a,h,M,eps);
% Output parameter:  d (approximate derivative using
%                   finite difference (f(h+h)-f(a))/h)
%                   err (approximation error)
%                   esterr (estimated approximation error)
% Input parameters:  f (name of function)
%                   fprime (name of derivative function)
%                   a (point at which derivative approx)
%                   h (stepsize)
%                   M (upper bound on second derivative)
%                   eps (error in f(a+h)-f(a))

d = (f(a+h)-f(a))/h;
err = abs(d-fprime(a));
esterr = h/2*M+2*eps/h;
```

A script that references the above function and plots the approximation error and the estimated error is given below. We will return to these results later to understand them better.

```
a=1; M=1; eps=10^(-15);
h=logspace(-1,-16,16);
n=length(h);
for i=1:n
    [d(i),err(i),esterr(i)]=MyDeriv(@sin,@cos,a,h(i),M,eps);
end
loglog(h,err)
```

Example 5: What happens if you call the function with only one or no output arguments, as below? (Also notice the use of `inline` to define `g` and `gprime` and the lack of the `@` in the calling sequence.)

```

g=inline('x.^ 2'); gprime=inline('2*x');
d=MyDeriv(g,gprime,a,h,M,eps)
MyDeriv(g,gprime,a,h,M,eps)

```

Example 6: We have seen how to pass in as an argument a function already defined in MATLAB (such as `sin`, `cos`), or a function defined using `inline` (note difference in calling script). Alternatively, we can pass in a user specified function that is not inline. Example: function `f1` (in file `f1.m`):

```

function y=f1(x);
% Input parameters:  fname (name of function)
%                   x (vector)
% Output parameter:  y (=f(x))

y = x.^2;

```

and function `df1` (in file `df1.m`):

```

function y=df1(x);
% Input parameters:  fname (name of function)
%                   x (vector)
% Output parameter:  y (=f(x))

y = 2*x;

```

Now you can call

```

MyDeriv(@f1,@df1,1,.1,10,.001)

```

13. Matrix operations

Defining matrices, an example

```
>> A=[ 1 2 3 4; -1 2 3 1; 1 1 1 1 ]           % What does this do?
```

Special matrices

```
>> eye(n)           % returns nxn identity matrix
```

Matrix Multiplication

```
>> C=A*B           % multiplies matrix A by matrix B provided  
>>                 % dimensionally correct (# columns of A=# rows of B)
```

Inverses and determinants

```
>> B=inv(A)        % returns inverse of A  
>> d=det(A)        % returns determinant of A  
>> A/B             % equals A* inv B
```

Solving systems

```
>> A\b             % returns solution to Ax=b
```
